

Rooted FC: How Trees Help Rainwater Score

THE AIM

Get the rain into the ground, where it can feed soil, plants, streams and springs later.

THE DANGER

On bare compacted ground, rain runs off the pitch before it gets a chance to score.

Team Sheet

Leaves United

Leaves defend against the attack of raindrops and stop the soil being smashed into a hard crust.

Stem City

Stems and trunks control midfield, slowing the match down and guiding water safely towards the ground.

Root Madrid

Roots attack the soil, opening channels and creating the scoring chances for water to go underground.

Worms Albion

Worms, fungi, insects and microbes coach from below, building tunnels and helping the whole team play better.

Soil Trafford

Healthy soil is the goalmouth. A good goal holds water after the match and releases it slowly later.

Runoff Rovers

Bare compacted ground loses possession. Water races downhill, carries soil away, and leaves the pitch.

Humans Are the Manager

The manager chooses the team shape: where to plant, where to protect young trees, where to keep animals off while roots grow, and where to watch what happens after rain.

Field Challenge

Stand on a slope after rain and ask:

- Where is water running away fastest?
- Where is the ground bare, hard or compacted?
- Where are roots already slowing water down?
- Where would you put your next defender?

Rain is the ball. Leaves defend. Roots attack. Soil is the goal. Humans manage the team.
